EXCEPTIONS, ASSERTIONS

EXCEPTIONS AND ASSERTIONS

- what happens when procedure execution hits an unexpected condition?
- get an exception... to what was expected
 - trying to access beyond list limits

test =
$$[1,7,4]$$

test $[4]$

→ IndexError

trying to convert an inappropriate type

→ TypeError

referencing a non-existing variable

а

→ NameError

mixing data types without coercion

'a'/4

→ TypeError

OTHER TYPES OF EXCEPTIONS

- already seen common error types:
 - SyntaxError: Python can't parse program
 - NameError: local or global name not found
 - AttributeError: attribute reference fails
 - TypeError: operand doesn't have correct type
 - ValueError: operand type okay, but value is illegal
 - IOError: IO system reports malfunction (e.g. file not found)

WHAT TO DO WITH EXCEPTIONS?

- what to do when encounter an error?
- fail silently:
 - substitute default values or just continue
 - bad idea user gets no warning
- return an "error" value
 - what value to choose?
 - complicates code having to check for a special value
- stop execution, signal error condition
 - in Python: raise an exception raise Exception ("descriptive string")

DEALING WITH EXCEPTIONS

Python code can provide handlers for exceptions

```
try:
    a = int(input("Tell me one number:"))
    b = int(input("Tell me another number:"))
    print(a/b)
    print ("Okay")
except:
    print("Bug in user input.")
print("Outside")
```

exceptions raised by any statement in body of try are handled by the except statement and execution continues after the body of the except statement

HANDLING SPECIFIC EXCEPTIONS

 have separate except clauses to deal with a particular type of exception

```
try:
    a = int(input("Tell me one number: "))
    b = int(input("Tell me another number: "))
    print("a/b = ", a/b)
    print("a+b = ", a+b)
except ValueError:
    print ("Could not convert to a number.")
                                                come up
except ZeroDivisionError:
    print("Can't divide by zero")
except:
    print("Something went very wrong.")
```

OTHER EXCEPTIONS

else:

 body of this is executed when execution of associated try body completes with no exceptions

finally:

- body of this is always executed after try, else and except clauses, even if they raised another error or executed a break, continue or return
- useful for clean-up code that should be run no matter what else happened (e.g. close a file)

6.00.01X LECTURE 8

EXAMPLE EXCEPTION USAGE

```
data = []
file name = input("Provide a name of a file of data ")
                                          Jump out if no file of that name
try:
    fh = open(file name, 'r')
except IOError:
    print('cannot open', file name)
else:
    for new in fh:
        if new != '\n':
             addIt = new[:-1].split(',') #remove trailir
                                          Close file in either case
             data.append(addIt)
finally:
    fh.close() # close file even if fail
```

- appears to correct read in data, and convert to a list of lists
- now suppose we want to restructure this into a list of names and a list of grades for each entry in the overall list

```
data = []
file name = input("Provide a name of a file of data ")
try:
    fh = open(file name, 'r')
except IOError:
    print('cannot open', file name)
else:
    for new in fh:
        if new != '\n':
            addIt = new[:-1].split(',') #remove trailing \n
            data.append(addIt)
finally:
                                                              Handle case of no grade;
But assumes two names!
    fh.close() # close file even if fail
gradesData = []
if data:
    for student in data:
        try:
            gradesData.append([student[0:2], [student[2]]])
        except IndexError:
            gradesData.append([student[0:2], []])
```

- works okay if have standard form, including case of no grade
- but fails if names are not two parts long

```
data = []
file name = input("Provide a name of a file of data ")
try:
    fh = open(file name, 'r')
except IOError:
    print('cannot open', file name)
else:
    for new in fh:
        if new != '\n':
             addIt = new[:-1].split(',') #remove trailing \n
            data.append(addIt)
                                                   Handle case of no grade; names!
Now allows for multiple names!
finally:
    fh.close() # close file even if fail
gradesData = []
if data:
    for student in data:
        try:
            name = student[0:-1]
            grades = int(student[-1])
            gradesData.append([name, [grades]])
        except ValueError:
             gradesData.append([student[:], []])
```

6.00.01X LECTURE 15

EXCEPTIONS AS CONTROL FLOW

- don't return special values when an error occurred and then check whether 'error value' was returned
- instead, raise an exception when unable to produce a result consistent with function's specification

```
raise <exceptionName>(<arguments>)
```

raise ValueError ("something is wrong"

keyword

name of error raise

typically a string with a message

EXAMPLE: RAISING AN EXCEPTION

```
def get ratios(L1, L2):
      """ Assumes: L1 and L2 are lists of equal length of numbers
          Returns: a list containing L1[i]/L2[i]
      ratios = []
      for index in range(len(L1)):
           try:
               ratios.append(L1[index]/float(L2[index]))
           except ZeroDivisionError:
manage flow of
program by raising
               ratios.append(float('NaN')) #NaN = Not a Number
           except:
               raise ValueError('get ratios called with bad arg')
      return ratios
```

17

EXAMPLE OF EXCEPTIONS

- assume we are given a class list for a subject: each entry is a list of two parts
 - a list of first and last name for a student
 - a list of grades on assignments

create a new class list, with name, grades, and an average

```
[[['peter', 'parker'], [80.0, 70.0, 85.0], 78.33333], [['bruce', 'wayne'], [100.0, 80.0, 74.0], 84.666667]]]
```

EXAMPLE CODE

```
[[['peter', 'parker'], [80.0, 70.0, 85.0]], [['bruce', 'wayne'], [100.0, 80.0, 74.0]]]
```

```
def get_stats(class_list):
    new_stats = []
    for elt in class_list:
        new_stats.append([elt[0], elt[1], avg(elt[1])])
    return new_stats

def avg(grades):
    return sum(grades)/len(grades)
```

ERROR IF NO GRADE FOR A STUDENT

• if one or more students don't have any grades, get an error

■ get ZeroDivisionError: float division by zero because try to

return sum (grades) / len (grades)

length is 0

OPTION 1: FLAG THE ERROR BY PRINTING A MESSAGE

decide to notify that something went wrong with a msg

```
def avg(grades):
    try:
        return sum(grades)/len(grades)
    except ZeroDivisionError:
        print('no grades data')
```

running on some test data gives

```
flagged the error
no grades data
[[['peter', 'parker'], [10.0, 5.0, 85.0], 15.41666666666666],
                                                         because avg did
not return anything
[['bruce', 'wayne'], [10.0, 8.0, 74.0], 13.8333333333333333],
[['captain', 'america'], [8.0, 10.0, 96.0], 17.5],
[['deadpool'], [],
                    Nonell
```

OPTION 2: CHANGE THE POLICY

decide that a student with no grades gets a zero

```
def avg(grades):
    try:
         return sum(grades)/len(grades)
    except ZeroDivisionError:
        print('no grades data')
                                    still flag the error
         return 0.0
```

running on some test data gives

```
no grades data
[[['peter', 'parker'], [10.0, 5.0, 85.0], 15.41666666666666],
                                                          now ayg returns 0
[['bruce', 'wayne'], [10.0, 8.0, 74.0], 13.833333333333333],
[['captain', 'america'], [8.0, 10.0, 96.0], 17.5],
[['deadpool'], [], 0.0]]
```

6.00.01X LECTURE 23

ASSERTIONS

- want to be sure that assumptions on state of computation are as expected
- use an assert statement to raise an AssertionError exception if assumptions not met
- an example of good defensive programming

EXAMPLE

```
def avg(grades):
    assert not len(grades) == 0, 'no grades data'
```

return sum(grades)/len(grades)

function ends if immediately if immediately if assertion not met

- raises an AssertionError if it is given an empty list for grades
- otherwise runs ok

ASSERTIONS AS DEFENSIVE PROGRAMMING

- assertions don't allow a programmer to control response to unexpected conditions
- ensure that execution halts whenever an expected condition is not met
- typically used to check inputs to functions procedures, but can be used anywhere
- can be used to check outputs of a function to avoid propagating bad values
- can make it easier to locate a source of a bug

WHERE TO USE ASSERTIONS?

- goal is to spot bugs as soon as introduced and make clear where they happened
- use as a supplement to testing
- raise exceptions if users supplies bad data input
- use assertions to
 - check types of arguments or values
 - check that invariants on data structures are met
 - check constraints on return values
 - check for violations of constraints on procedure (e.g. no duplicates in a list)

27
